Localized histograms

Template Matching

-
- Similar to convolutions, we pass a template image across a moving window and calculate a “similarity score”.
 - The output is an array/“similarity heatmap” that contains the most likely matches.
 - Different criteria for similarity.

Example

Matching Result

Detected Point

Hough Transform

Motivation: Lane detection

R. Klette. Concise Computer Vision.
©Springer-Verlag, London, 2014.

-
- Use a (robust) edge detector to get a binary edge map.
 - Check if the remaining pixels make a segment.
 - This last step is sensible to noise. Instead, we look at the lines in their **parameter space**.

Image vs Parameter space

-
- However, the parameter space (a,b) has a small problem: you cannot represent vertical lines with finite values.
 - Instead, we use the **Hesse normal form** to parameterize a line.
 - In this parameter space, points = sinusoidal curves.

Circle detection

Circle detection: Fixed radius

Each point in geometric space (left) generates a circle in parameter space (right). The circles in parameter space intersect at the (a, b) that is the center in geometric space.

Circle detection: Unknown radius
